

WHAT IS A DOCKER ?

Credit : Ellen

Development

Lets say You created an Application

And that's working fine in
your machine

Production

**But in Production it
doesn't work properly**

Developers experience it a lot

That is when the Developer's famous words are spoken

Your application is
not working

It works on my machine

The Reason could be due to :

- Dependencies
- Libraries and versions
- Framework
- OS Level features
- Microservices

That the developers machine has but
not there in the **production environment**

DOCKER

We need a standardized way to package the application with its **dependencies** and deploy it on any environment.

Docker is a tool designed to make it easier to **create, deploy, and run** applications by using **containers**.

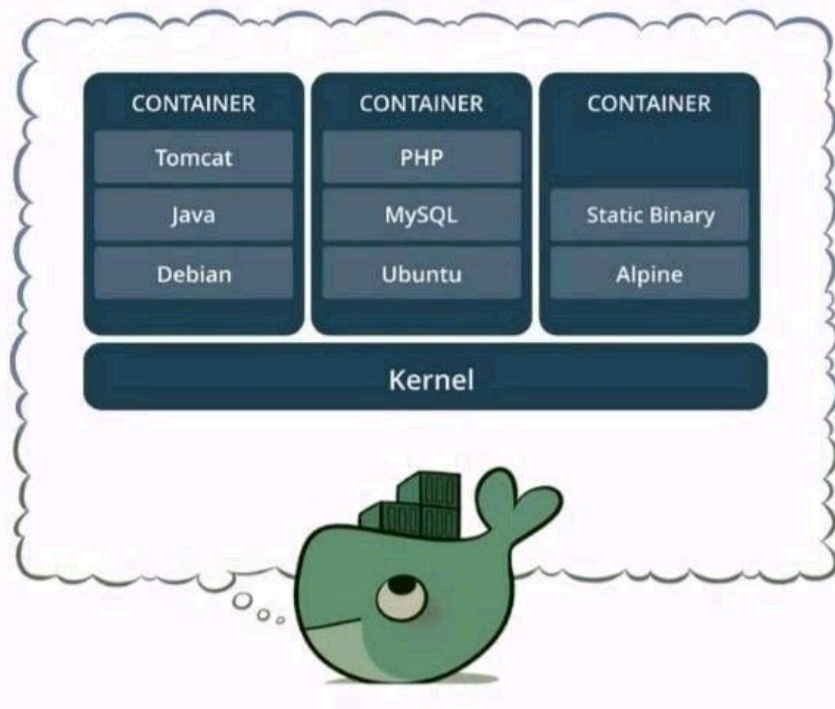

How Does Docker Work?

Docker packages an application and all its **dependencies** in a **virtual container** that can run on any Linux server.

Each container runs as an **isolated process** in the user space and take up **less space** than regular VMs due to their layered architecture.

So it will always work the same
regardless of its environment
